Abstract: Problem statement: Speech compression is an important issue in the modern digital speech communication. The functionality of bitrates scalability also plays significant role, since the capacity of communication system varies all the time. When considering tonal speech, such as Thai, tone plays important role on the naturalness and the intelligibility of the speech, it must be treated appropriately. Therefore these issues are taken into account in this study. Approach: This study proposes a modification of flexible Multi-Pulse based Code Excited Linear Predictive (MP-CELP) coder with bitrates scalabilities for tonal language speech in the multimedia applications. The coder consists of a core coder and bitrates scalable tools. The high pitch delay resolutions are applied to the adaptive codebook of core coder for tonal language speech quality improvement. The bitrates scalable tool employs multi-stage excitation coding based on an embedded-coding approach. The multi-pulse excitation codebook at each stage is adaptively produced depending on the selected excitation signal at the previous stage. Results: The experimental results show that the speech quality of the proposed coder is improved above the speech quality of the conventional coder without pitch-resolution adaptation. Conclusion: From the study, the proposed approach is able to improve the speech compression quality for tonal language and the functionality of bitrates scalability is also developed.

Key words: Thai speech, Multi-Pulse based Code Excited Linear Predictive (MP-CELP), speech compression, bitrates scalability, Conjugate-Structure Algebraic Code Excited Linear Predictive (CS-ACELP), Tone (T), bitrates scalable, High Pitch Delay Resolutions (HPDR), MOS scores

INTRODUCTION

In the present days, the digital communications are widely developed (Jabrane et al., 2007). The audio, images, video or data information can be transmitted through wire or wireless network channels. Simultaneously, the number of users to access these networks increases rapidly. Consequently, channel capacity has to be increased, signal compression aims to perform this (Chompun et al., 2000). Since the multimedia applications such as videophone and videoconference on ATM and Internet are widely used, the high quality speech codes are highly demanded. These kinds of applications require special considerations for packet loss. To overcome this problem, it is to realize a scalable coder where the synthesized speech signal can be decoded from the received packets, which contain only a part of the whole encoded bitstream. One of standardization activities for such areas is undergoing at the MPEG-4 (Nomura et al., 1998; Chomphan, 2010b).

In 1995, Conjugate-Structure Algebraic Code Excited Linear Predictive (CS-ACELP) coding was developed and standardized as ITU G.729 speech coding at 8 kbps. Later, MP-CELP coder has been proposed to be a scalable coder around this bitrates. This flexible coder employs the multi-pulse excitation which the number of pulses in fixed-entry codebook is selective for bitrates scalability and multiple bitrates functionality according to the MPEG-4 CELP speech coder requirements, (Nomura et al., 1998; Chomphan, 2010b; Rahim and Islam, 2009).

In MP-CELP, amplitudes or signs for multi-pulse excitation are simultaneously vector quantized. To improve speech quality for background noise conditions, the adaptive pulse location restriction method are applied (Ozawa and Serizawa, 1998). This coder operates at various bitrates ranging from 4-12 kbps utilizing the flexibility in multi-pulse excitation coding (Chomphan, 2010b; Singh et al., 2007).

As for tonal language, such as Thai, a syllable is composed of consonants, vowels and tone (Wutiwivatchai and Furui, 2007).
The smallest structure of sounds or syllables in Thai is composed of one vowel unit or one diphthong, one, two or three consonants and a tone. The structure can be represented as illustrated in Fig. 1. Ci is initial consonant, Cf is final consonant, V is vowel and T is tone.

The significant difference between tonal and toneless language is Tone (T). In tonal language, the words of different tones yield their distinguished meaning. By using the standard speech coder such as CS-ACELP with tonal language, it showed the degraded speech quality when compared to those of toneless language. The reason is that the tone information precision is not enough for tonal language, (Chompun et al., 2000; Wutiwiwatchai and Furui, 2007).

This study proposes a bitrates scalable tonal language speech coder based on a multi-pulse based code excited linear predictive coding (Taumi et al., 1996; Ozawa et al., 1996; Al-Haddad et al., 2009). The proposed coder provides the bitrates scalabilities which is effective in multimedia communications. Moreover, this coder is improved for the tonal language speech by applying the high pitch delay resolutions to retain the tone information precision.

MATERIALS AND METHODS

Bitrates scalable MP-CELP coder: The operation principle for bitrates scalable MP-CELP coder can be separated into 2 parts, MP-CELP core coder and bitrates scalable tool.

MP-CELP core coder: The MP-CELP core coder achieves a high coding performance by introducing a multi-pulse vector quantization as depicted in Fig. 2 (Taumi et al., 1996; Ozawa et al., 1996). The input speech of 10 ms frame is processed through Linear Prediction (LP) and pitch analysis. The LP coefficients are quantized in the Line Spectrum Pairs (LSP) domain. The pitch delay is encoded by using an adaptive codebook. The residual signal for LP and the pitch analysis is encoded by the multi-pulse excitation scheme. The multi-pulse excitation signal is composed of several non-zero pulses. The pulse positions are restricted in the algebraic-structure codebook and determined by an analysis-by-synthesis approach, (Laflamme et al., 1991; Chomphan, 2010a).

Fig. 2: MP-CELP core coder

Bitrates scalable tool: This study uses at most 3 stages of the bitrates scalable tools according to the MPEG-4CELP requirement as illustrated in Fig. 3 (Chomphan,
Tonal language speech coder: In Thai speech, there are 5 different tones, mid(0), low(1), falling(2), high(3) and rising(4), whose characteristics are depicted in Fig. 4 (Wutiwiwatchai and Furui, 2007). Each graph represents the behavior of fundamental frequency (f0) in a period of syllable time where f0 is the inverse of pitch delay time. Though, f0 indicates the periodicity of voice. Investigating the difference between Thai male and Thai female f0 behaviors, Thai female f0 change rate is almost all more than Thai male f0’s, (Thathong et al., 2000).This is why the Thai female speech quality encoded by CS-ACELP coder is lower than the Thai male speech quality (Chompun et al., 2000). Hence, detecting f0 with high precision yields the improvement of the tonal language speech quality.Since pitch delay (or f0) significantly involves in tone of tonal language, this study proposes an improvement of the bitrates scalable MP-CELP coder by applying the High Pitch Delay Resolutions (HPDR) technique to the pitch analysis of the core coder. The HPDR at pitch fraction of 1/2, 1/3 and 1/4 is adopted to the pitch analysis, consequently, it causes the increments of bitrates as 200, 400 and 400 bps respectively. The HPDR technique is done by including the pitch fraction analysis within the conventional pitch analysis which finds the optimum fraction around the prior pitch delay integer of the conventional pitch analysis.

In order to find the adaptive excitation for the proposed technique, the FIR filter based on a Hamming windowed \( \sin(x) / x \) function truncated at ±11 and padded with zeros at ±12 is adopted to weight the excitation in the pitch fraction analysis.

RESULTS

The coding quality of the proposed coder was evaluated subjectively and objectively by using 36 tested sentences from 10 men and 10 women, some of them were shown in Table 2.

The effectiveness of the high pitch delay resolutions applied to the conventional coder was evaluated using average segmental SNRs and MOS scores. Comparison tests of each grouped bitrates were conducted and shown in Table 3 and 4.

DISCUSSION

For the objective test (SegSNR), the results showed that both male and female speech quality, every grouped bitrate, the HPDR at pitch fraction of 1/4 gave the maximum value. The order of speech quality from the best to the worst was 1/4's, 1/3's, 1/2's and conventional’s respectively. For the subjective test (MOS score), the results were corresponding to those of the objective test.

From the experimental results, the more high resolution be used the more speech quality be obtained. This indicates that the proposed HPDR technique brings the better pitch precision which causes an improvement of the coding quality for tonal language.

CONCLUSION

In this study, a modification of bitrates scalable tonal language speech compression has been proposed. The compression algorithm consists of a MP-CELP core coder and the bitrates scalable tools. The high pitch delay resolutions are applied to adaptive codebook of core coder for tonal speech quality improvement. The results show that the coding quality of the proposed coder is better than the conventional coder for Thai language. The proposed approach can support a number of coding rates.

ACKNOWLEDGEMENT

The researchers is grateful to Digital Signal Processing Research Laboratory of Chulalongkorn University for providing the facilities and technical supports to this research and Kasetsart University at Si Racha campus for the research scholarship through the board of research.
