Abstract: This study aims to evaluate the effect of *Chamaemelum nobile* (Cn) intravenous injection on cardiovascular and renal function of normal rats. Intravenous bolus injection of Cn at the dose of 50, 100 and 200 mg kg\(^{-1}\), produced dose dependent reduction in arterial blood pressure (p<0.001). Significant reduction in heart frequency was observed after Cn injection at a dose of 100 and 200 mg kg\(^{-1}\) (p<0.001). Perfusion of Cn aqueous extract at a dose of 200 mg kg\(^{-1}\) h\(^{-1}\) caused a significant increase in urine output after three hours of perfusion (p<0.001). Significant increase in urinary sodium and potassium excretion was observed from the first (p<0.05) to the third hour (p<0.001) of Cn perfusion. Urinary chlorure excretion increased after two hours of perfusion (p<0.001). However, glomerular filtration rate remained unchanged after Cn perfusion (p<0.05). We conclude that the Cn aqueous extract possess potent acute hypotensive effect in normal rats. In addition Cn perfusion may affect renal function to increase urine and electrolytes excretion.

Key words: Ethnopharmacology, mean arterial pressure, urine output, urine electrolytes

INTRODUCTION

Medicinal plants represent a valuable source of new therapeutic agents\(^1\). According to the World Health Organisation, more than 80% of the world’s population-primarily those of developing countries-relied on plants and plant-derived medicines for their healthcare\(^2\). More than 231 medicinal plants are communally used in the Moroccan pharmacopoea\(^3\). As a part of Moroccan territory, Tafilalet region is a repository of plants in the treatment of cardiovascular diseases\(^4,5\). Increasing urine and electrolytes excretion may be beneficial in the treatment of hypertension\(^6\). Studies have been established the diuretic effect of several plants extract in normal and hypertensive rats\(^6,14\). Furthermore, the observed diuretic activity was associated in several cases with a reduction in arterial blood pressure\(^15,16\).

*Chamaemulum nobile* (Cn) is a plant belonging to Asteraceae family. The aqueous extract of this plants is used in the treatment of diabetes and cardiovascular diseases\(^4\). To our knowledge, no scientific informations are available concerning the cardiovascular effect of Cn aqueous extract. This study was carried out to evaluate the effect of intravenous injection of Cn on arterial blood pressure and renal function in normal rats.

housed under standard environmental conditions (23±1°C, 55±5% humidity and a 12 h light/dark cycle) and had free access to water and ad libitum standard laboratory diet.

**Surgery:** The rats were anaesthetized by an intraperitoneal injection of Inactin at a dose of 50 mg kg$^{-1}$ of body weight. They were then placed on a thermostated table to keep them at a constant temperature.

**Experimental procedures:** Effect of intravenous bolus injection of Cs aqueous extract on MAP and HR.

Arterial blood pressure was measured from the carotid artery via heparinized polyethylene cannula PE-50 connected to a blood pressure transducer Gould Statham transducer allowing the monitoring of blood pressure.

The desired dose of drugs and Cs lyophilized aqueous extract were dissolved in a constant volume of saline 200 µL and injected in the form of bolus injection via a catheters PE-10 inserted into the external jugular vein followed by a saline flush (200 µL). Animals were allowed to equilibrate for at least 30 min before administration of Cn aqueous extract.

Six rats received graded doses (50, 100 and 200 mg kg$^{-1}$) of Cn aqueous extract which was administered intravenously and the corresponding blood pressure and heart rate were recorded immediately. A control group received bolus intravenous injection of saline 10 min separate each intravenous injection. Mean Arterial Blood Pressure (MAP) is a sum of diastolic blood pressure and 1/3 pulse pressure (mmHg).

**Renal effect of Cn aqueous extract perfusion:** Two catheters PE50, one filled with physiological saline solution (NaCl), the other filled with heparinized physiological saline solution were introduced respectively to the right jugular vein of the cardiac side and to the left jugular vein of the encephalic side. The first serves to perfuse the test solutions and the second for blood sampling. The bladder was also catheterized in order to collect urine for determination of different parameters. At the end of the experiment, the animals were sacrificed by cutting their carotids, urine and plasma were conserved at –20°C until biochemical analysis.

The group one served as an untreated control, whereas the second group was given a perfusion of Cn at a dose of 200 mg kg$^{-1}$ h$^{-1}$. The third group received furosemide, as a reference drug at a dose of 0.1 mg kg$^{-1}$ h$^{-1}$. The experimental protocol adopted has two phases: A control phase of 30 min when saline solution was perfused and an experimental phase of four hours for Cn aqueous extract and furosemide perfusion. Five urine and blood samples were taken; at the start of control phase and within the experimental phase at the start, 1, 2 and 3 h of treatment. All experiments were performed in fasted rats.

**Parameters:** Blood samples were collected from the jugular vein. Urinary samples were collected from the catheterized bladder. Creatinine was evaluated by colorimetric methods, according to the manufacturer's protocol (Boerhinger, Germany) using a spectrophotometer (HITACHI Model U-2001).

Sodium, potassium and chloride levels were determined in urine samples using an auto-analyser (HITACHI 911-Boehringer).

Glomerular filtration rate was evaluated by the clearance of creatinine.

**Statistical analysis:** Results were expressed as mean±SEM of six observations. ANOVA was used to calculate the levels of significance for comparison made within group and between groups using Graphpad prism 4.0 software.

**RESULTS**

**Effect of intravenous injection of Cn aqueous extract on arterial blood pressure:** Lyophilized Cn aqueous extract was injected intravenously at three different doses: 50, 100, 200 mg kg$^{-1}$ to anesthetized normal rats. Figure 1 shows, arterial blood pressure evolution after intravenous injection of Cn aqueous extract. The three used doses produced a significant reduction in arterial blood pressure 2 min after intravenous injection (p<0.001). Maximal reduction was observed 2 min after the intravenous injection of 200 mg kg$^{-1}$ of CN aqueous extract (p<0.001). The observed fall in arterial blood pressure disappear progressively causing a return to the baseline values after 10 min of intravenous injection. However, in the control group, intravenous injection of 200 µL of saline solution did not affect arterial blood pressure.

**Effect of intravenous injection of Cn aqueous extract on heart rate:** Intravenous injection of Cn aqueous extract at a dose of 100 and 200 mg kg$^{-1}$ produced reduction in heart rate with p<0.01 and p<0.001 respectively (Fig. 2). No significant change in heart rate was observed after 5 min of Cn intravenous
Fig. 1: Effect of bolus intravenous injection of aqueous Cn extract (50, 100 and 200 mg kg\textsuperscript{-1}) on arterial blood pressure (mmHg) of anesthetized normal rats.

Effect on urine output: Intravenous perfusion of Cn aqueous extract at a dose of 200 mg kg\textsuperscript{-1} h\textsuperscript{-1} produced a significant increase in urine output three hours after the start of perfusion. However, furosemide perfusion significantly increases the urine output after one hour of intravenous perfusion. The increase in urine output was sustained until three hours of perfusion period. No change in the urine output was observed during three hours of intravenous of saline solution (Fig. 3).

Fig. 2: Effect of bolus intravenous injection of aqueous Cs extract (50, 100 and 200 mg kg\textsuperscript{-1}) heart rate (beats min\textsuperscript{-1}) of anesthetized normal rats. Data are expressed means±SEM, n = 6 per group. *: p<0.05, **: p<0.01, ***: p<0.001

injection. The intravenous injection of Cn aqueous extract at a dose of 50 mg kg\textsuperscript{-1} did not significantly affect the heart rate.

Effect on Glomerular Filtration Rate (GFR): No significant change in GFR was observed after intravenous perfusion on CN at a dose of 200 mg kg\textsuperscript{-1} h\textsuperscript{-1} (p>0.05). Furosemide treated group showed significant increase in GFR after two hours of intravenous perfusion (p<0.01). Additional increase was observed at the end of experiments (p<0.001) (Fig. 4).

Fig. 3: Effect of intravenous administration of aqueous Cn extract (500 mg kg\textsuperscript{-1} h\textsuperscript{-1}) on urinary excretion of water (mL h\textsuperscript{-1}). Data are expressed as means±SEM, n = 6 rats per group. **: p<0.01, p<0.001 when compared to the respective control values.

Fig. 4: Effect of intravenous administration of aqueous Cn extract (500 mg kg\textsuperscript{-1} h\textsuperscript{-1}) on glomerular Filtration Rate (GFR) (mL kg\textsuperscript{-1} h\textsuperscript{-1}). Data are expressed as means±SEM, n = 6 rats per group. **: p<0.01, p<0.001 when compared to the respective control values.
Fig. 5a: Effect of intravenous administration of aqueous Cn extract (500 mg kg\(^{-1}\) h\(^{-1}\)) on urinary excretion of sodium (UNa\(^{+}\)V) (µEq min\(^{-1}\)). Data are expressed as means±SEM, n = 6 rats per group. **: p<0.01, p<0.001 when compared to the respective control values.

**Effect on urinary sodium excretion:** Figure 5a shows changes in urinary electrolytes excretion after intravenous perfusion of Cn aqueous extract. When perfused at a dose of 200 mg kg\(^{-1}\) h\(^{-1}\), Cn aqueous extract produced a significant increase in the urinary sodium excretion after two hours of perfusion (p<0.001). Additional one hour perfusion did not cause further increase in urinary sodium excretion. Furosemide perfusion when perfused at a dose of 0.1 mg kg\(^{-1}\) h\(^{-1}\) produced significant and sustained increase in urinary sodium excretion from the first to the third hour of perfusion.

**Effect on urinary potassium excretion:** In Fig. 5b, intravenous perfusion of Cn aqueous extract at a dose of 200 mg kg\(^{-1}\) h\(^{-1}\) caused a significant increase in urinary potassium excretion after two (p<0.05) and three (p<0.01) hours of intravenous perfusion. Furosemide perfusion produced significant increase in urinary potassium excretion from the first hour (p<0.05) to the third hour (p<0.001).

**Effect on urinary chlorure excretion:** Figure 5c shows the time evolution of urinary chlorure excretion. Intravenous injection of Cn aqueous extract caused a significant increase two hours after the start of perfusion (p<0.001) no additional increase was observed at the third hour of perfusion (p<0.001). Significant increase in urinary chlorure excretion was observed after one hour (p<0.001) in furosemide perfused group (p<0.001).

Fig. 5c: Effect of intravenous administration of aqueous Cn extract (500 mg kg\(^{-1}\) h\(^{-1}\)) on urinary excretion of chlorur (UCl\(^{-}\)V) (µEq min\(^{-1}\)). Data are expressed as means ± S.E.M, n=6 rats per group. **p<0.01, p<0.001 when compared to the respective control values.

DISCUSSION

Cn is world wildly used in the treatment of various diseases\(^{[17]}\). Our previous works demonstrated the potent hypoglycaemic effect of Cn aqueous extract in streptozotocin-induced diabetic rats\(^{[18]}\). This work was carried out to evaluate the hypotensive and diuretic of...
intravenous injection of Cn aqueous extract. Cn aqueous extract was lyophilized and injected intravenously in bolus mode at a dose of 50, 100 and 200 mg kg\(^{-1}\) of body weight and arterial blood pressure was monitored via a catheter placed in the carotid artery. In spite of same disadvantages, the used method of blood pressure measurement was largely used in the screening of cardiovascular effect of drugs\(^{[19]}\). The intravenous injection of Cn aqueous extract produce a dose dependent reduction in arterial blood pressure. The duration of the hypotensive effect was lasted after 5 min of the intravenous injection. Previous studies have established the hypotensive effect of plant extract after intravenous injection\(^{[20-23]}\). Furthermore, Cn aqueous extract produced significant reduction in heart frequency, so Cn aqueous extract may reduce arterial pressure via at least a reduction in heart rate\(^{[23]}\). However, it is not exclude that the Cn aqueous extract may act affect the adrenergic system to reduce vascular tone\(^{[21,23,24]}\). The rapid onset of arterial pressure reduction leads us to postulate the probable implication of sympathetic or cholinergic system in the hypotensive effect of Cn aqueous extract. In normal rats blood pressure is strictly controlled via a complex nervous and hormonal function\(^{[25]}\), the observed reduction in the arterial blood pressure witness the strong hypotensive effect of Cn aqueous extract.

In the second part of this study, Cn aqueous extract was perfused intravenously at a rate of 200 mg kg\(^{-1}\) h\(^{-1}\), urine volume and electrolytes were measured in order to evaluate the renal effect of Cn aqueous extract. Furosemide, a loop diuretic agent, was used as a reference drug\(^{[26]}\). We demonstrated that the Cn increases diuresis. Furthermore, sodium, potassium and chloride urinary excretion was increased. Previous studies demonstrated diuretic activity of medicinal plants\(^{[9,13,26-31]}\). The increase in urine electrolytes may be probably due to the inhibition of renal Na\(^+\)–K\(^+\) pump that would lead to a reduction in Na\(^+\) and K\(^+\) reabsorption leading thus to an osmotic water flow into the lumen and diuresis\(^{[15]}\). Plant mineral content may probably increase urinary and electrolytes excretion\(^{[32]}\). Cn did not produce renal artery vasodilatation since GFR was unchanged during perfusion, previous studies have reported the increase of GFR in parallel with increasing diuresis\(^{[15,31]}\). It is well established that increasing diuresis and electrolytes excretion may reduce arterial blood pressure\(^{[13,20,22,26]}\). Thus, Cn aqueous extract may reduce blood pressure after chronic administration.

Photochemical investigation reported the abundance of flavonoid product in Cn\(^{[33]}\). Flavonoids possess beneficial cardiovascular effect and may be thus responsible of the observed hypotensive and diuretic effect\(^{[34]}\).

We conclude the Cn aqueous extract possess a dose dependent hypotensive and diuretic effects when administered intravenously.
