Abstract: The widely acknowledged fact is that the economic growth based only on an export of the raw materials cannot be stable for a long time and thereupon the financial support of an innovative activity gets of a special urgency. To provide higher and steady rates of an economy growth it is necessary to carry out a transition to an innovative way of the development and to spur the creation of the hi-tech manufactures. At the same time it does not mean the automatic termination of the raw materials extraction. The stocks of some kinds of them make the state the leading one in the world. The aim of the article is to review the main aspects of the selection of indicators to measure innovation in enterprises. To improve the efficiency of innovation investment enterprises must evaluate the potential of the company and on this basis to identify priority areas of investments completed. The paramount value for the given problem decision has a choice of the indicators for the estimation of the enterprises innovative activity. The paper substantiates the need for regression analysis when selecting indicators. A mathematical model using different combinations of options indicators of innovation activities of enterprises. Mathematical models are made and used for three generalized purposes such as for an explanation, a prediction and a management. The study suggested indicators for assessing the potential of the enterprise. It is necessary to prioritize the financing of innovation enterprises. In the article conclusions about possible directions for further research and also presents some limitations of the analysis.

Keywords: Finance Companies, Correlation and Regression Analysis, Performance Evaluation of Innovation

Introduction

Nowadays a modernization and a transition to innovative development of all public life spheres are the key priorities for Russia development. The considerable financial resources are required for the realization of these country priority goals and it causes the interest to the problems connected with the search and the choice of the most suitable sources for the innovative process financial maintenance.

The generally recognized fact is that the economic growth based only on the raw materials export cannot be stable for a long time and thereupon the financing of the enterprises innovative activity gets a special urgency. It is necessary to carry out the transition to an innovative way of a development to provide higher and steady rates of the economy growth and to energize the hi-tech manufactures creation. At the same time it does not mean the automatic stoppage of the extraction of the raw materials which stocks are the leading size ones of the separate kinds not only in our country but in the world. The country future development should cater for the accelerated rates of the innovative technologies adoption for the account of the raw materials disposal means and the following increase of the stuff processing level including.

Various aspects of the development of innovation in the works analyzed by (Shumpeter, 1961; Yakovets, 1999; Kondratiev, 1984; Porter, 1985; Kuznets, 1955; Drucker, 2012; 2013). The financing of innovation activities of enterprises and analyze the potential of the enterprise is considered in works by (Folomev and Revazov, 2001; Nechaev and Prokopeva, 2013; Uvarova, 2011; Gluschenko, 2009; Sharpe et al., 1998; Janeway, 2012; Atkinson and Ezell, 2012).

But in the existing works are poorly studied the directions of investment for stimulation of the enterprises innovative activity.

Methods

As a rule an innovative activity is characterized by such problem as a high degree of an uncertainty and a risk and therefore the important principles of an
The linear equation of a plural regress for revealing the dependence between indicators of the enterprises innovative activity looks like Equation 1:

\[ p_i = b_0 + \sum_{j=1}^{k} b_{jk} \]  

(1)

Where:

- \( p_i \) = The productive indicator of the enterprises innovative activity values received as a result of the substitution of factorial signs corresponding values in the regress equation
- \( b_0 \) = Free factor
- \( b_{jk} \) = Model parameters (regress factors)
- \( k_j \) = Factorial quantity indicators of the enterprises innovative activity
- \( j = 1, n \) = Quantity of factors

The formula (1) allows to investigate the dependences between the indicators of the enterprises innovative activity and to define those of them which render the greatest value on the end results.

For the construction of mathematical models the various variants of a indicators combination of the enterprises innovative activity were used. Some mathematical models are presented below.

The plural regress equation for the dependence research of the innovative production shipped volume in million ruble, a number of the enterprise research divisions in units, the innovations expenses of the enterprise in million ruble, the number of the joint projects for the research and investigation performance in which the organization participates in the units, looks like the following Equation 2:

\[ p_1 = 838,75 + 194,01k_1 + 17,28k_2 + 189,16k_3 \]  

(2)

Where:

- \( k_1 \) = A number of the enterprise research divisions in units
- \( k_2 \) = The enterprise expenses of for the innovations in million ruble
- \( k_3 \) = The number of joint projects for the research and investigation performance in which the organization participates in the units
- \( p_1 \) = Volume of shipped innovative production in million ruble

For the decision of a factors selection problem and the expediency of an inclusion of this or that factor in a model we will calculate the special indicators of a correlation for the selection of the indicators. Let’s construct a correlation matrix (Table 1).

Now we can see that the greatest influence on the volume of the shipped production is rendered by the expenses for the innovations and number of the enterprise research divisions.
Table 1. The special factors of a correlation for formula 2

<table>
<thead>
<tr>
<th></th>
<th>$p_1$</th>
<th>$k_1$</th>
<th>$k_2$</th>
<th>$k_3$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$p_1$</td>
<td>1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>$k_1$</td>
<td>0,4</td>
<td>1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>$k_2$</td>
<td>0,6</td>
<td>0,5</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>$k_3$</td>
<td>0,3</td>
<td>0,5</td>
<td>0,3</td>
<td>1</td>
</tr>
</tbody>
</table>

The plural regress equation for the dependence research of the innovative production shipped volume in million ruble, a number of the enterprise research divisions in units, the innovations expenses of the enterprise in million rubles, the number of the joint projects for the research and investigation performance in which the organization participates in units looks like the following Equation 3:

$$p_2 = \text{0,038}k_1 + 5,12k_2 + 0,02k_3$$

(3)

Where:

- $k_1 =$ The enterprise volume of the investments of in a fixed capital in million ruble
- $k_2 =$ Number of joint projects for the research and investigation performance in which the organization participates in units
- $k_3 =$ Volume of the shipped innovative production in million ruble
- $p_2 =$ The expenses of the enterprise for the innovations in million ruble. Let’s calculate the special factors of a correlation (Table 2)

Now we can see that the enterprise expenses are mostly influenced by the volume of the shipped innovative production and the volume of the investments into a fixed capital.

The plural regress equation for the dependence research of the research division number from such factors as the number of the enterprise workers having a higher education, the number of the enterprise workers having various scientific degrees, the number of the joint projects for the researches and investigation performance in which the organization participates looks like the following Equation 4:

$$p_3 = -0,08 + 0,27k_1 + 0,11k_2 + 0,03k_3$$

(4)

Where:

- $k_1 =$ The number of the enterprise workers having a higher education in thousand people
- $k_2 =$ The number of the enterprise workers having various scientific degrees
- $k_3 =$ The number of the joint projects for the performance of the researching and investigating in which the organization participates in units
- $p_3 =$ The number of the enterprise research divisions in units. Let’s calculate the special factors of a correlation (Table 3)

</tbody>
</table>
The selected indicators are divided into four special kinds of the enterprise potentials. The indicators of the personnel potential characterize a composition, a structure and a quality of the enterprise personnel. The scientific potential shows a research component of the enterprise. The economic potential includes the indicators characterizing the volumes of an innovative production and the enterprise investment into a fixed capital. The financial potential shows the profit and the expenses of the enterprise connected to an innovative activity. The basic advantage of the offered indicators is the choice of the most widespread of them covering all kinds of the special potentials.

Discussion

For the Russian Federation the problems connected with the successful innovative projects realization are extremely actual taking into consideration the increasing technological degradation of the manufacture. Even the scaled investments in the old technological structure cannot bring a proportional return and lead to the growth of a costs inflation only. Thereupon a mass character of the innovative projects will allow our country to reduce an existing raw dependence, to modernize the economy and to create the competitive advantages of the Russian Federation in the international market what will finally promote the increase of the citizen’s life quality level. The future development of the country should be directed to the accelerated rates of the innovative technologies introduction using the incomes from a primary raw materials selling with a stage-by-stage increasing the level of its processing.

We used information from a variety of methods for selecting assessment indicators of innovative enterprises. We analyzed the indicators used by the various techniques in the estimation of the enterprises innovative activity and the efficiency of its financing: (Gadzhiev et al., 2009; Kamenskaja, 2011; Lenchuk and Vlaskin, 2005; Raevsky, 2006). As a result, based on our research and using regression analysis we have proposed indicators for full machining capacity assessment enterprise.

Authors all indicators grouped in the potentials. For example, suggests to allocate personal potential, information potential, management potential and others (Zaikina, 2010). (Korobeynikov et al., 2000) believe that it is important analysis of the scientific potential.

We shared all the indicators on the four-building: Personal potential, scientific potential, economic potential, financial potential. As the result of the analysis made by us it was revealed that the personnel, scientific, economic and financial potentials have the greatest influence on the innovative activity. The analysis made by us is supported by the practical experience of many enterprises conducting the innovative activity. For example, the personnel component of the actions being done will have the crucial importance for any enterprise engaged in the innovations. The personnel possessing higher knowledge and qualification are more productive than the other categories of the employees and are capable to generate the effective ways of realization these or those production processes. The other potentials revealed by us possess not the smaller importance too.

Conclusion

Thus, we used the correlation and regression analysis for the purpose of the most significant indicators selection for an estimation of innovative activity financing efficiency of the enterprises. The correlation and regression analysis allows to define the laws of the studied phenomena development and to understand the difficult mechanism of cause and effect interrelations and dependences between the economic indicators more deeply. Besides, the correlation and regression analysis allows researchers to reveal by means of supervision not only obvious (known) but also the implicit (latent) dependences and to express them in the form of the formulas or mathematically to simulate the phenomena or processes. Thus mathematical models are made and used for three generalized purposes such as for an explanation, a prediction and a management. In the course of the innovative-active enterprises financing arises the necessity of achievement of the similar purposes such as the estimations of enterprise potential, the forecasting and on the basis of the received results the definition of the most effective tools for financing the enterprises innovative activity. The above-mentioned shows that the application of the correlation and regression analysis is quite reasonable.

A number of limitations of the analysis performed have to be mentioned. First, the use of regression analysis is possible when there is sufficient number of observations for the study. In practice, it is considered that the number of observations should be not less than 5.6 times the number of factors. Secondly, the initial set of values should be qualitatively homogeneous. Thirdly, the fact that correlation does not give reason to believe that one of the variables is the reason for the change, or what variables are causally linked, but not observed effect of the third factor.

Further studies can be directed to the use of indicators to assess the potential of enterprise. It is necessary to identify the problems in the innovation activities of enterprises and determining funding to address these issues. For example, if after the analysis of the potentials revealed that the company has problems in personal potential, it is necessary to program being developed to attract young professionals to work in the field of innovation.
In addition, further studies may be associated with the development of tools (algorithms, models, methods) to identify promising areas of the enterprise.
