# Reliability of Simple 3-Dimnesional Consecutive k-Out-of-n: F Systems 

M. Gharib, E.M. El-Sayed and I.I.H. Nashwan<br>Department of Mathematics, Faculty of Science, Ain Shams University, Egypt

#### Abstract

Problem statement: In this study, the reliability of some special cases of a 3-dimnesional consecutive k-out-of-n: F system and k-within consecutive ( $2,2,2$ ) -out-of- ( $\mathrm{m}, 2,2$ ): F system were discussed. Approach: The 3 dimensional systems is a generalization of 1 and 2 dimensional, systems. Projections from 3 dimensional systems to 2 or 1 dimension as special cases is very helpful to find the reliability of these 3 dimensional systems. Results: Many reliability expressions for the 3-dimensional consecutive $\left(k_{1}, k_{2}, k_{3}\right)$-out-of- ( $m, n, \ell$ ): F system for some special values of $\mathrm{k}_{1}, \mathrm{k}_{2}, \mathrm{k}_{3}, \mathrm{~m}, \mathrm{n}, \ell$ are presented. Further, the reliability of k -within (2, 2, 2)-out-of-(m,2,2): F system using Markov chains is considered. Conclusion/Recommendations: In general, it is difficult to find the reliability of $\left(\mathrm{k}_{1}, \mathrm{k}_{2}, \mathrm{k}_{3}\right)$ -out-of- ( $\mathrm{m}, \mathrm{n}, \ell$ ): F system, we studied special cases of this system and recommend generalizing the result for any value of $\mathrm{k}_{1}, \mathrm{k}_{2}, \mathrm{k}_{3}, \mathrm{~m}, \mathrm{n}, ~ \varrho$. This study presented the reliability formulas of simple 3D systems using results of consecutive k-out-of-n: F systems and 2D consecutive k-out-of-n: F systems and Markov chains.

Key words: (1, 2 and 3) D-consecutive k-out-of-n: F system, k-within ( $\mathrm{k}_{1}, \mathrm{k}_{2}, \mathrm{k}_{3}$ ) -out-of- (m,n, $)$ : F system, Markov chains

## INTRODUCTION

The consecutive k-out-of-n: F system has been extensively studied in recent years (Bollinger and Salvia, 1982; Chen and Hwang, 1985; Derman et al., 1982; Shantikumar, 1982; Cluzeau and Keller, 2008; Lambiris and Papastavridis, 1985). The system is specified by n , the number of components, where each component either functions or fails. The system fails if at least k consecutive components fail. The 2Dconsecutive k-out-of-n: F system was introduced by Salvia and Lasher (1992) by generalizing the notion of the consecutive k-out-of-n: F system. A 2Dconsecutive k-out-of-n: F system (denoted by $\mathrm{k}^{2} \mid \mathrm{n}^{2}$ : F) was defined as a square grid of side n (containing $\mathrm{n}^{2}$ components). The system fails if there is at least one square of side $k(1 \leq k \leq n)$ that contains all failed components. Zuo (1993) proposed a more general model of 2D- consecutive k-out-of-n: F system (denoted by $\left.k_{1} k_{2} \mid m n: F\right)$. It is a rectangular grid of dimension $m \times n$ (containing m.n components). The system fails if there is at least one rectangle grid of dimension $\mathrm{k}_{1} \times \mathrm{k}_{2}(1 \leq$ $\left.\mathrm{k}_{1}, \mathrm{k}_{2} \leq \mathrm{m}, \mathrm{n}\right)$ that contains all failed components (Yamamoto and Akiba, 2005). Boehme et al. (1992) and Yamamoto et al. (2008) defined a consecutive ( $\mathrm{k}_{1}, \mathrm{k}_{2}$ ) or ( $\mathrm{k}_{1}, \mathrm{k}_{2}$ ) -out-of- (m,n): F system. In this case the system fails if at least one rectangle of dimension $k_{1} \times k_{2}$ or $\mathrm{k}_{2} \times \mathrm{k}_{1}$ that contains all failed components occurs.

Similarly the 3D- consecutive k-out-of-n: F system (denoted by $\mathrm{k}^{3} \mid \mathrm{n}^{3}$ : F) is defined as a cube of side n containing $\mathrm{n}^{3}$ components. The system fails if there is at least one cube of side $\mathrm{k}(1 \leq \mathrm{k} \leq \mathrm{n})$ that contains all failed components (Akiba and Yamamoto, 2002; Akiba et al., 2004). Also more general model of 3D- consecutive k-out-of-n: F systems (denoted by $\mathrm{k}_{1} \mathrm{k}_{2} \mathrm{k}_{3}$ |mnl: F). It is a cuboid of dimension $\mathrm{m} \times \mathrm{n} \times \ell$ (containing m.n. $\ell$ components). The system fails if there is at least one cuboid of dimension $\mathrm{k}_{1} \times \mathrm{k}_{2} \times \mathrm{k}_{3}\left(1 \leq \mathrm{k}_{1}, \mathrm{k}_{2}, \mathrm{k}_{3}, \leq \mathrm{m}, \mathrm{n}, \mathrm{l}\right)$ that contains all failed components. This study gives the reliability of simple 3D systems using results of consecutive 1 and 2 D - consecutive k-out-n: F system in addition to a special case of 3D-dimension system which is k -within (2,2,2)-out-of-(m,2,2): F system, this system consists of ( $\mathrm{m}, 2,2$ ) cuboid, the system fails if there is at least k failed components in any $(2,2,2)$ cuboid.

## MATRIALS AND METHODS

The 3-dimensional systems is a generalization of 1 and 2 -dimensional, system, projections from 3dimensional systems to 2 or 1 dimension as special cases is very helpful to find the reliability of special cases of the 3 dimensional systems. This study gives the reliability of some special cases of the 3-dimensional systems. To describe the problem, we introduce the following notations and assumptions.

[^0]J. Math. \& Stat., 6 (3): 261-264, 2010

## Notations:

- p,q: Components reliability (unreliability) of component where $\mathrm{p}+\mathrm{q}=1$
- $g_{k}(n, j)$ : Configuration of no consecutive $k$ failed components from $j$ through the all $n$ components which equal $\sum_{i=0}^{\text {gilb }[j k]}(-1)^{i}\binom{n-i k}{j-i k}\binom{n-j+1}{i}$
- $\alpha(\mathrm{m}, \mathrm{j})$ : Configuration of no connected 2 components in $(\mathrm{m}, 2)$ system.
- $\quad \mathrm{R}(\mathrm{k} ; \mathrm{n} ; \mathrm{p})$ : The reliability of a consecutive k-out-ofn : F system
- $R\left(\left(k_{1}, k_{2}\right) ;(m, n) ; p\right)$ : The reliability of $a$ consecutive (k1,k2)-out-of-(m,n): F system
- $R\left(\left(k_{1}, k_{2}, k_{3}\right) ;(m, n, 1) ; p\right)$ : The reliability of $a$ consecutive ( $\mathrm{k} 1, \mathrm{k} 2, \mathrm{k} 3$ )-out-of-( $\mathrm{m}, \mathrm{n}, \mathrm{l})$ : F system
- $\quad \mathrm{R}(\mathrm{k}-(2,2,2) ;(\mathrm{m}, 2,2) ; \mathrm{p})$ : The reliability of a kwithin (2,2,2)-out-of- (m,2,2): F system
- $\mathrm{S}_{\mathrm{r}}$ : Random variable count the failed component of cuboid $(2,2,2)$ in the $r^{\text {th }}$ layer
- $\quad \mathrm{P}_{\mathrm{k}}$ : Markov transition probability matrix
- $\quad P_{k}(i j)$ : Element of transition probability matrix with status i and j

## Assumption:

- Each component and the whole system can only be either functioning or failed
- All components are mutually s-independent

Lemma: For the k-within (2,2,2)-out-of-(m,2,2): F system, if $\mathrm{i}, \mathrm{j}$ the statuses of Markov chains, the transition probability matrix denoted $\mathrm{P}_{\mathrm{k}}$ of the system will be:

$$
P_{k}(i j)= \begin{cases}\binom{4}{j} p^{4-j} q^{j} & i+j<k \\ 0 & i+j \geq k\end{cases}
$$

and:

$$
\mathrm{R}(\mathrm{k}-(2,2,2) ;(\mathrm{m}, 2,2) ; \mathrm{p})=\sum_{\mathrm{j}=0}^{4} \mathrm{P}_{\mathrm{k}}^{\mathrm{m}}(0 \mathrm{j})
$$

Proof: If $i+j<k$ then the number of failed components in the layer $\mathrm{r}+\mathrm{l}$ does not depend on the number of failed components in the layer r , so:

$$
\begin{aligned}
P_{k}(i j)=P\left(S_{r+1}=j S_{r}=i\right) & =\frac{P\left(S_{r+1}=j, S_{r}=i\right)}{P\left(S_{r}=i\right)} \\
= & \frac{\binom{4}{j}\binom{4}{i} p^{8-(i+j)} q^{(i+j)}}{\binom{4}{i} p^{4-i} q^{i}} \\
& =\binom{4}{j} p^{4-j} q^{j}
\end{aligned}
$$

If $i+j \geq k$ the system will fail, so:

$$
P\left(S_{r}=\mathrm{i}, \mathrm{~S}_{\mathrm{r}+1}=\mathrm{j}\right)=0 \Rightarrow \mathrm{P}_{\mathrm{k}}(\mathrm{ij})=0
$$

Hence; the reliability of the system will be of the form:

$$
\mathrm{R}(\mathrm{k}-(2,2,2) ;(\mathrm{m}, 2,2) ; \mathrm{p})=\sum_{\mathrm{j}=0}^{4} \mathrm{P}_{\mathrm{k}}^{\mathrm{m}}(0 \mathrm{j})
$$

## RESULT

The reliability formulas of simple 3D systems: The reliability of a consecutive (k,1,1)-out-of-(m,l,l): F system is the same as the reliability of consecutive k -out-of-n: F system. Therefore from (Zuo, 1993) if $\mathrm{k} \leq \mathrm{m}, \mathrm{n}, \ell$ :

$$
\begin{align*}
R((k, 1,1,) ;(m, 1,1,) ; p) & =R(k ; m ; p) \\
& =\sum_{j=0}^{m-\sin [m / k]} g_{k}(m, j) p^{m-j} q^{j} \tag{1}
\end{align*}
$$

Also:

$$
\begin{align*}
R((1, k, 1) ;(1, n, 1) ; p) & =R(k ; n ; p) \\
& =\sum_{j=0}^{n-g i b[n \mid k]} g_{k}(n, j) p^{n-j} q^{j} \tag{2}
\end{align*}
$$

and:

$$
\begin{align*}
& \mathrm{R}((1,1, \mathrm{k}) ;(1,1,1) ; \mathrm{p})=\mathrm{R}(\mathrm{k} ; 1 ; \mathrm{p}) \\
&=\sum_{\mathrm{j}=0}^{1-\text { gilb }[1 \mathrm{l}]} \mathrm{g}  \tag{3}\\
& g_{k}(1, j) \mathrm{p}^{1-j} \mathrm{q}^{j}
\end{align*}
$$

A consecutive ( $1,1,1$ )-out-of-( $\mathrm{m}, \mathrm{n}, \ell$ ): F system reliability is the same as the reliability of a series system consisting of m.n.l components. Therefore:
$\mathrm{R}((1,1,1) ;(\mathrm{m}, \mathrm{n}, \mathrm{l}) ; \mathrm{p})=\mathrm{R}(1 ; \mathrm{mn} \ell ; \mathrm{p})=\mathrm{p}^{\mathrm{m} . \mathrm{n} . \ell}$
The reliability of a consecutive ( $\mathrm{m}, \mathrm{n}, \ell$ )-out-of( $\mathrm{m}, \mathrm{n}, \ell$ ): F system is the same as the reliability of a parallel system consisting of m.n. $\ell$ components. Therefore:
$\mathrm{R}((1,1,1) ;(\mathrm{m}, \mathrm{n}, \ell) ; \mathrm{p})=\mathrm{R}(\mathrm{mn} \ell ; \mathrm{mn} \ell ; \mathrm{p})=1-\mathrm{q}^{\mathrm{m} . \mathrm{n} . \ell}$
The reliability of a consecutive ( $k, 1,1$ )-out-of( $\mathrm{m}, \mathrm{n}, \ell$ ): F system. In this case the system consists of $l$ parallel ( $\mathrm{m}, \mathrm{n}$ )-matrix, any $(\mathrm{m}, \mathrm{n})$-matrix is considered as a consecutive (k,l)-out-of-(m,n): F system. In accordance with our definition, the system will fail if at least one row of any ( $m, n$ )-matrix includes kconsecutive failed elements occurs. Then the system operating if all of the rows (consider as a consecutive k-out-of-m: F system) are operating. Since the elements fail independently, the rows and the matrices fail independently.

The probability that the ( $\mathrm{m}, \mathrm{n}$ ) matrix does not fail is equal to the product of the probabilities that the rows of this matrix do not fail, therefore:
$\mathrm{R}((\mathrm{k}, 1) ;(\mathrm{m}, \mathrm{n}) ; \mathrm{p})=[\mathrm{R}(\mathrm{k} ; \mathrm{m} ; \mathrm{p})]^{\mathrm{n}}$
and:
$R((\mathrm{k}, 1,1) ;(\mathrm{m}, \mathrm{n}, \ell) ; \mathrm{p})=[\mathrm{R}(\mathrm{k} ; \mathrm{m} ; \mathrm{p})]^{\mathrm{n} . \ell}$
Analogously for the consecutive (l,k,l)-out-of( $\mathrm{m}, \mathrm{n}, \ell$ ): F system, the reliability function:
$\mathrm{R}((1, \mathrm{k}, 1) ;(\mathrm{m}, \mathrm{n}, \ell) ; \mathrm{p})=[\mathrm{R}(\mathrm{k} ; \mathrm{n} ; \mathrm{p})]^{\mathrm{m} . \ell}$
And for the consecutive ( $1,1, \mathrm{k}$ )-out-of-(m,n, $\ell)$ : F system, the reliability function:
$\mathrm{R}((1,1, \mathrm{k}) ;(\mathrm{m}, \mathrm{n}, \ell) ; \mathrm{p})=[\mathrm{R}(\mathrm{k} ; \ell ; \mathrm{p})]^{\mathrm{m} . \mathrm{n}}$
A consecutive ( $\mathrm{m}, \mathrm{k}, \mathrm{l}$ )-out-of-( $\mathrm{m}, \mathrm{n}, \ell$ ): F system, in this case, the system consists of $\ell$ parallel ( $\mathrm{m}, \mathrm{n}$, )-matrix. Any matrix is considered as a consecutive ( $\mathrm{m}, \mathrm{k}$ )-out-of( $\mathrm{m}, \mathrm{n}$ ): F system. In accordance with our definition, the system will fail if k-consecutive columns each including $m$ failed elements occur of any ( $m, n$, )-matrix. Then we consider the column as new "element" with failure probability $q^{m}$ and reliability $1-q^{m}$ and any ( $m, n$ ) matrix as a consecutive k-out-of-m: F system, having the reliability $R\left(k ; 1 ; 1-q^{m}\right)$, therefore:
$\mathrm{R}((\mathrm{m}, \mathrm{k}, 1) ;(\mathrm{m}, \mathrm{n}, \ell) ; \mathrm{p})=\left[\mathrm{R}\left(\mathrm{n}, \mathrm{k} ; 1-\mathrm{q}^{\mathrm{m}}\right)\right]^{\ell}$
Analogously, for consecutive (k,n,l)-out-of( $\mathrm{m}, \mathrm{n}, \ell$ ): F system, the reliability will be:
$\mathrm{R}((\mathrm{k}, \mathrm{n}, 1) ;(\mathrm{m}, \mathrm{n}, \ell) ; \mathrm{p})=\left[\mathrm{R}\left(\mathrm{k}, \mathrm{m} ; 1-\mathrm{q}^{\mathrm{n}}\right)\right]^{\ell}$
and, for consecutive ( $\mathrm{m}, 1, \mathrm{k}$ )-out-of-( $\mathrm{m}, \mathrm{n}, \ell$ ): F system, the reliability will be:
$R((m, 1, k) ;(m, n, \ell) ; p)=\left[R\left(k, n ; 1-q^{m}\right)\right]^{n}$
and, for consecutive (k,1,l)-out-of-(m,n, $\ell$ ): F system, the reliability will be:
$\mathrm{R}((\mathrm{k}, 1, \ell) ;(\mathrm{m}, \mathrm{n}, \ell) ; \mathrm{p})=\left[\mathrm{R}\left(\mathrm{n}, \mathrm{k} ; 1-\mathrm{q}^{\ell}\right)\right]^{\mathrm{n}}$
and, for consecutive ( $1, \mathrm{k}, \ell$ )-out-of-( $\mathrm{m}, \mathrm{n}, \ell$ ): F system, the reliability will be:
$\mathrm{R}((1, \mathrm{k}, \ell) ;(\mathrm{m}, \mathrm{n}, \ell) ; \mathrm{p})=\left[\mathrm{R}\left(\mathrm{m}, \mathrm{k} ; 1-\mathrm{q}^{\ell}\right)\right]^{\mathrm{m}}$
and, for consecutive ( $1, \mathrm{n}, \mathrm{k}$ )-out-of-(m,n, $\ell)$ : F system, the reliability will be:
$R((1, n, k) ;(m, n, \ell) ; p)=\left[R\left(m, k ; 1-q^{n}\right)\right]^{m}$
A consecutive ( $\mathrm{m}, \mathrm{n}, \mathrm{k}$ )-out-of-( $\mathrm{m}, \mathrm{n}, \ell$ ): F system $(\mathrm{k} \leq \ell)$. The system fails if k consecutive ( $\mathrm{m}, \mathrm{n}$ )-matrices each including m.n failed elements. Then we can consider-matrices as new "element" with failure probability $q^{m . n}$ and reliability $1-q^{m . n}$, the system equivalents to consecutive k-out-of- $\ell: \mathrm{F}$ system having the reliability $\mathrm{R}\left(\ell, \mathrm{k} ; 1-\mathrm{q}^{\mathrm{m} . \mathrm{n}}\right)$.

Analogously, for consecutive ( $\mathrm{m}, \mathrm{k}, \ell$ )-out-of$(m, n, \ell): F$ system $(k \leq n)$, the system equivalents to consecutive k-out-of-n: F system having the reliability $\mathrm{R}\left(\mathrm{n}, \mathrm{k} ;, 1-\mathrm{q}^{\mathrm{m} . \ell}\right)$ and for consecutive ( $\mathrm{k}, \mathrm{n}, \ell$ )-out-of( $\mathrm{m}, \mathrm{n}, \ell$ )-: F system $(\mathrm{k} \leq \mathrm{m})$, the system equivalents to consecutive k-out-of-m: F system having the reliability $\mathrm{R}\left(\mathrm{m}, \mathrm{k} ; 1-\mathrm{q}^{\mathrm{n} . \ell}\right)$.

A consecutive (1,2,1)-or-(2,1,1)-out-of-(m,2,1): F system. The system consists of ( $\mathrm{m}, 2$ )-matrix i.e., the reliability of the system is the same as $(1,2)$-or-( 2,1 )-out-of- $(\mathrm{m}, 2)$ : F system, because it fails if 2 connected components fail, therefore from (El-Sayed, 1998):

$$
\begin{align*}
& \mathrm{R}((1,2,1)-\text { or }-(2,1,1) ;(\mathrm{m}, 2,1) ; \mathrm{p}) \\
& =\mathrm{R}((1,2)-\text { or }-(2,1) ;(\mathrm{m}, 2) ; \mathrm{p})  \tag{16}\\
& =\sum_{\mathrm{j}=0}^{\mathrm{m}} \alpha(\mathrm{~m}, \mathrm{j}) \mathrm{p}^{2 \mathrm{~m}-\mathrm{j}} \mathrm{q}^{\mathrm{j}} \\
& \alpha(m, j)= \begin{cases}1 & j=0 \\
2 m & j=1 \\
2 & j=m \\
\alpha(m-1, j)+ & 1<j<m \\
2 \sum_{i=1}^{j} \alpha(m-i-1, j-i) & \\
0 & \text { otherwise }\end{cases} \tag{17}
\end{align*}
$$

Also:

$$
\begin{align*}
& R\binom{(1,2,1)-\text { or }-(2,1,1) ;}{(2, n, p) ; p}=R\binom{(1,2)-\text { or }-}{(2,1) ;(n, 2) ; p}  \tag{18}\\
& \quad=\sum_{j=0}^{n} \alpha(n, j) p^{2 n-j} q^{j}
\end{align*}
$$

and:

$$
\begin{align*}
& \mathrm{R}\binom{(1,2,1)-\text { or }}{-(2,1,1) ;(1,2,1) ; p}=\mathrm{R}\binom{(1,2)-\text { or }}{-(2,1) ;(1,2) ; \mathrm{p}}  \tag{19}\\
& \quad=\sum_{\mathrm{j}=0}^{1} \alpha(1, \mathrm{j}) \mathrm{p}^{21-\mathrm{j}} \mathrm{q}^{\mathrm{j}}
\end{align*}
$$

Reliability of k -within (2,2,2)-out-of-( $\mathrm{m}, 2,2$ ): F system.

According the lemma 1 we can directly find the transitive probability matrix and compute the reliability of the system.

Example: Compute $\mathrm{R}(4-(2,2,2) ;(3,2,2) ; \mathrm{p})$ :

$$
\begin{aligned}
& \mathrm{P}_{4}=\left(\begin{array}{cccc}
\mathrm{p}^{4} & 4 \mathrm{p}^{3} \mathrm{q} & 6 \mathrm{p}^{2} \mathrm{q}^{2} & 4 \mathrm{pq}^{3} \\
\mathrm{p}^{4} & 4 \mathrm{p}^{3} \mathrm{q} & 6 \mathrm{p}^{2} \mathrm{q}^{2} & 0 \\
\mathrm{p}^{4} & 4 \mathrm{p}^{3} \mathrm{q} & 0 & 0 \\
\mathrm{p}^{4} & 0 & 0 & 0
\end{array}\right) \\
& P_{4}^{3}(00)=p^{12}+8 p^{11} q^{2}+28 p^{10} q^{2}+56 \mathrm{p}^{9} \mathrm{q}^{3} \\
& \mathrm{P}_{4}^{3}(01)=4 \mathrm{p}^{11} \mathrm{q}+32 \mathrm{p}^{10} \mathrm{q}^{2}+114 \mathrm{p}^{9} \mathrm{q}^{3}+208 \mathrm{p}^{8} \mathrm{q}^{4} \\
& P_{4}^{3}(02)=6 p^{10} q^{2}+48 p^{9} q^{3}+132 p^{8} q^{4}+168 p^{7} q^{5} \\
& P_{4}^{3}(03)=4 p^{9} q^{3}+16 p^{8} q^{4}+24 p^{7} q^{5}+16 p^{6} q^{2} \\
& P_{4}^{3}(03)=4 p^{9} q^{3}+16 p^{8} q^{4}+24 p^{7} q^{5}+16 p^{6} q^{2} \\
& R(4-(2,2,2) ;(3,2,2) ; p)=\sum_{j=0}^{4} P_{4}^{3}(0 j) \\
& R(4-(2,2,2) ;(3,2,2) ; p)=p^{12}+12 p^{11} q+66 p^{10} q^{2} \\
& +222 p^{9} q^{3}+356 p^{8} q^{4}+192 p^{7} q^{5}+16 p^{6} q^{2}
\end{aligned}
$$

## DISCUSSION

In general, it is difficult to find the reliability of $\left(\mathrm{k}_{1}, \mathrm{k}_{2}, \mathrm{k}_{3}\right)$-out-of- ( $\mathrm{m}, \mathrm{n}, \mathrm{c}$ ): F system. Thus, in this article, we found the reliability of some special cases in an explicit form. Projections from 3 dimensional systems to 2 or 1 dimension as special cases is very helpful to find the reliability of these 3 dimensional systems. Also we found the reliability of $k$-within (2,2,2)-out-of-(m,2,2): F system using Markov Chains.

## CONCLUSION

In this study, we concluded the reliability of some special cases of ( $\mathrm{k}_{1}, \mathrm{k}_{2}, \mathrm{k}_{3}$ )-out-of-( $\mathrm{m}, \mathrm{n}, \mathrm{c}$ ): F system.

Also, the reliability of $k$-within (2,2,2)-out-of-(m,2,2): F system is derived easily using Markov Chains.
